(54) Title: APPARATUS AND METHOD FOR DELIVERY OF LIGHT TO SKIN

(57) Abstract

Improvements to a system for the process of hair removal which employs a collimated laser beam delivered to a target. These improvements include a reflector for reflecting back light scattered from the surface and improving light coupling into the tissue, use of an *array* of micro lenses for focusing the incident beam, and an annular ring to thin the epidermis and upper dennis to reduce blood volume in the illuminated area, and increase flux density at significant depths.

1 2 Apparatus and method for delivery of light to skin 3 4 This invention relates to light delivery and in 5 particular to a apparatus and method for delivery of a 6 beam of light to a target area beneath the surface of 7 the skin. 8 9 Most particularly this invention relates to an. 10 apparatus and method designed to improve the delivery 11 of laser or other light to targets underneath the skin 12 surface especially, but not solely, to assist in 13 optical hair removal. That is, this invention relates 14 to the use of optical based techniques in dermatology 15 for the removal of unwanted stains, pigment, marks, 16 hairs, or other sub-surface features. 17 18 Lasers and, in some cases, other light sources have 19 found increasing use in dermatology for the treatment 20 or removal of sub-surface lesions. These techniques 21 have largely been based on the concepts of selective 22 photothermolysis. This implies that the laser 23 wavelength is chosen to match a characteristic 24 absorption associated with the target but not with the 25 surrounding tissue. Thus, absorption of the laser

**WO** 98/52481 PCT

2

PCT/GB98/01523

1 light and the subsequent heating is largely restricted 2 to that target. In addition, the process also involves choosing the duration of the laser pulse to maximise 3 the temperature of the target before significant 4 conduction to the surrounding tissue can take place. 5 6 For example, a 30 nanosecond pulse from a Nd:YAG laser 7 at 1.06µm is strongly and selectively absorbed in the 8 blue-black pigments of common tattoos. Since the 9 tattoo pigments accumulate in granules of micron size, such a short pulse is almost wholly used to heat and 10 fragment the granule before significant heating of the 11 surroundings takes place. 12 13 14 More recently techniques have been described which 15 relate to the removal of unwanted hair using lasers. 16 In one approach a Nd:YAG laser similar to the one mentioned above is used. Since there is little or no 17 18 natural selective absorption at this wavelength, an 19 external chromophore must first be applied and 20 persuaded to migrate down the hair shaft to the base to 21 provide an appropriate target. 22 23 In an alternative approach a ruby laser at 0.694nm is In this approach the melanin content of the hair 24 25 shaft provides the selectively absorbing chromophore. 26 2.7 The ruby laser was introduced many years ago for 28 removal of tattoos. For tattoo removal the laser 29 output was "Q-Switched" - that is, the energy was 30 compressed to a pulse of only a few 10's of 31 nanoseconds. Such a pulse, whilst ideal for tattoo 32 granule fragmentation, is neither necessary nor 33 desirable for the more thermal process of hair removal. 34 35 For hair removal, the ruby laser is operated in its so-36 called "normal mode" wherein the pulse duration is

PGT/GB98/01523 ₩O 98/52481

3 1 extended to about 1 millisecond. The real target is 2 not the hair itself. Following the selective absorption of the laser light along the buried hair 3 shaft and the heating of the.latter, the overall 4 process relies on the conduction of heat from the shaft 5 6 to surrounding. tissue, in particular to two zones, the 7 first near the shaft base (papilla); and the second 8 approximately a third of the way down the shaft, known 9 as the bulge. Direct absorption into these zones is possible, and can contribute to their heating since 10 they also contain an enhanced level of melanin. These 11 12 zones are believed to contain the cells responsible for 13 hair growth, and damage to them via this process of laser heating should lead to permanent hair removal or 14 15 at least substantially delayed regrowth. 17 A simple approach is to apply light with the required

16

18 19

20

21

level of energy density to an area of skin. The level is chosen to give sufficient heating to destroy the target zones whilst leaving the surrounding tissue undamaged. In practice this required level lies between 10 and 50 Jim'.

22 23 24

25

26

2.7

28

29

30

Various techniques have been used or proposed to assist in improving the efficiency of the process. These techniques include precooling of the area, cooling during the process, selective cooling of the epidermis using millisecond cryogen spray, use of optical transmitting gels to improve coupling into the tissue, convex shaped applicators, and devices to draw folds of skin which may receive radiation from either side.

31 32

33 Whereas there may be both advantages and disadvantages 34 to varying degrees in all of these approaches, it is 35 manifest that there is a need for a beam delivery 36 system that addresses the problems of sub-surface

4

1 targeting from both an optical and a biological 2 viewpoint. 3 4 According to a first aspect of the present invention there is provided an apparatus for delivery of a beam 5 6 of light to a target area beneath the surface of the 7 skin comprising means to deliver a collimated light 8 beam, and light delivery means to increase the light 9 energy density at said target area while minimising the 10 light energy density at the surface of the skin. 11 12 Preferably said means to improve delivery comprises 13 means to improve effective light coupling into tissue. 14 Said means to improve effective light coupling may 15 comprise recovery means to recover light reflected on 16 incidence with the skin. 17 18 Said recovery means may comprise a reflective surface. 19 20 Preferably the apparatus comprises means to thin the 21 skin above the target area. Said means may stretch the 22 skin. 23 24 Preferably the apparatus comprises means to reduce 25 local blood flow in the target area. 26 27 Preferably the means to stretch the skin acts also to 28 reduce the local blood flow. 29 30 Preferably the apparatus comprises means to subject the 31 area adjacent the target area to vacuum suction. 32 33 Said means may comprise a member adapted to be sealed 34 to the skin and to subject the area of skin surrounding 35 the target area to a vacuum. 36

PCT/GB98/01523 WO 98/52481

Preferably said member has an annular channel. Said 1 channel may be ring shaped or oval. Preferably said channel is adapted to be positioned

with the channel opening in contact with the skin.

5

4

6 Preferably the apparatus comprises means to increase light flux density at the depth of the target. Said means may redistribute an incident collimated beam 9 prior to its incidence with the skin.

10

Said redistribution means may comprise an array of 11 Preferably said lenses are of short focal 12 Preferably said array is selected to increase 13 length. 14 the flux density at a nominated depth.

15 16

17

18

Preferably the apparatus comprises recovery means to recover light reflected on incidence with the skin; means to thin the skin above the target; and means to increase light flux at the depth of the target.

19 20

21 Preferably the light beam is a laser light beam.

22 23

24 25

26

The apparatus may further include known techniques such as tissue precooling and/or selective cooling of the epidermis and/or use of optical transmitting gels and/or convex shaped applicators and/or devices to draw 27 folds of skin which may receive radiation from either side and/or other features already known.

28 29

30 According to a second aspect of the present invention 31 there is provided a method for delivery of a beam of 32 light to a target area beneath the surface of the skin 33 comprising the step of using an apparatus according to the first aspect of the invention. 34

35

36 According to a further aspect of the present invention

WO 98/52481

1	there is provided a method for delivery of a beam of
2	light to a target area beneath the surface of the skin
3	comprising the steps of directing a collimated light
4	beam onto the surface of the skin, and using a light
5	delivery means to increase the light energy density at
6	said target area while minimising the light energy
7	density at the surface of the skin.
8	
9	Embodiments of the present invention will now be
10	described by way of example only with reference to the
11	accompanying drawings in which:
12	
13	Figure 1 shows a apparatus in accordance with an
14	aspect of the present invention.
15	
16	Figures 2a and 2b illustrate the effect on fluence
17	at the skin surface and at a given depth beneath
18	the surface, of increasing the area of surface
19	illumination of the skin;
20	
21	Figures 2c and 2d also illustrate the effect on
22	fluence at the skin surface and at a given depth
23	beneath the surface, of increasing the area of
24	surface illumination;
25	
26	Figure 2e is a graphical representation of the
27	rate of increase of the effective fluence at depth
28	with increase of surface beam diameter;

7

Figure 5 shows an annular ring in accordance with an aspect of the present invention.

3

5

6 7

9

10

Referring to the drawings, this apparatus, generally designated 1 is designed to provide a combination of both optical and mechanical means of improvement of the sub-surface flux density of a beam delivered by a beam delivery system to the target areas. Although this apparatus has its origins in improvements related to beam delivery for hair removal, other optical processes requiring selective sub-surface damage may benefit.

11 12

A beam delivery system normally comprises a light 13 source and means for its delivery to a target area. A 14 15 first improvement to this system is the provision of a 16 sealed annular ring 4 as shown in Figure 5. This annular ring is placed adjacent the tissue surface 2 17 above the target. The region of surface skin in the 18 19 annulus is subject to a vacuum by connection of a vacuum pump to vacuum outlet 8 and is thus drawn 20 21 upwards to form raised areas 11. In one dimension this 22 is similar to proposals for obtaining a fold of tissue to allow transillumination. However the instant 23 24 configuration takes advantage of the fact that dermal 25 blood is taken towards the region 11 under vacuum in the direction of arrows 10 and thus away from the 26 27 central circular core area 12.

2829

30

31

32

33

Although the ruby laser wavelength corresponds to a minimum in the absorption spectrum of blood, residual absorption of blood remains a competing unwanted factor in the utilisation of the laser light. Thus reduction of local blood volume due to adjacent vacuum suction provides an important advantage.

3435

36 A second and more significant effect is that the

drawing up into the annulus of a small amount of tissue 2 13 effectively stretches the skin 2 throughout the 3 circular core 12. Even mild stretching of around 10% of the diameter - 2mm in Figure 5 where the central 4 5 area has a diameter of 20mm - translates to a thinning of the epidermis and upper dermis of 20%. Since the reduction in light flux with depth into the skin is 7 8 exponential this thinning provides an increase in flux 9 density of as much as 80% at a depth of 3mm 10 corresponding to the depth of the papilla. This 11 effect, in conjunction with the reduction of the local 12 blood volume, reduces the required incident flux 13 density by a significant factor. These effects also 14 improve the selectivity of the process. 15 16 This aspect of the invention is thus directed 17 principally at providing a physical means of reducing 18 beneficially both the blood content of the tissue 19 immediately below the exposed area, and the thickness 20 through which light must penetrate to reach structures 21 at depths of several millimetres. 22 23 Both these effects, that is the biological and the 24 physical, combine to improve the fraction of light 25 fluence (energy per unit area) at the required depth 26 for a given fluence at the surface. 27 28 Usually if the target structures are at some 29 significant depth into tissue, a problem arises in 30 trying to balance the need for a minimum fluence at 31 depth required to effect the necessary damage, whilst 32 sparing structures nearer the surface that normally see 33 a significantly higher fluence. This aspect of the 34 invention acts directly to improve this situation and 35 thus helps in sparing surface tissue and components.

36

WO 98/52481 PCT

PCT/GB98/01523

A handpiece incorporating such a ring 4 has its most 1 immediate application in a process such as hair removal where selective damage to the follicles 2-4mm deep is required. Other applications, for example the visualisation of dermal blood vessel anatomy for 5 diagnostic purposes would also benefit. 6 The influence of light scattering in tissue is to 8 substantially increase the volume of tissue 9 10 experiencing some of the light compared with the 11 initially exposed area. The larger the initial area, 12 the less this affects the fluence at a given depth other than near the perimeter of the area. 13 14 15 This phenomenon is best understood by reference to Figures 2a and 2b. 16 17 18 In Figure 2a the spread of the energy present. in the 19 beam, that is, the expansion of the beam due to 20 scattering, is indicated approximately by following a line 30 representing the average direction of scattered 21 The energy incident on the surface is within 22 an area 20 of 1mm<sup>2</sup>, but at a depth of 3mm 50°s of the 23 24 incident energy can be found within a much larger area 25 21 of lcm<sup>2</sup>. Thus the surface fluence is reduced by about a factor of 200. (This assumes that no 26 '27 absorption takes place.) 28 29 If a second area 22, adjacent to the first area 20 and also of 1 mm<sup>2</sup>, is illuminated with equal energy, then 30 31 the fluence (energy density) on the surface remains 32 constant. It can be seen from Figure 2b that at depth 33 the energy from the second source in area 23 very 34 largely overlaps that of the first source in area 21.

Thus the fluence at depth has almost doubled for no

change in surface fluence.

35

36

WO 98/52481

10

PCT/GB98/01523

Figures 2c and 2d show the same effect but with sample 1 2 fluences typical of laser hair removal. 3 This process continues with the fraction of the surface 4 5 fluence effective at depth increasing with size of The rate of increase slows to give a 6 illuminated area. 7 constant fraction when the illuminated area of the 8 surface is several cm'. This function is sketched in 9 Figure 2e, in which line 40 shows the fluence at 3mm depth (in J/cm<sup>2</sup>) plotted against the beam diameter at 10 the surface (in mm). 11 12 13 The numbers used in this example are illustrative only 14 but are close to those encountered in skin. In the 15 case of hair removal, a target is approximately 3 mm 16 deep and therefore a certain level of fluence will be' 17 required at that depth to achieve the required 18 therapeutic effect. 19 20 This therapeutic fluence is determined by the 21 absorption of light from lasers such as ruby and 22 alexandrite into the melanin within and around the 23 follicle. The epidermis and upper dermis, however, 24 contain the same absorbing chromophore as that present 25 in the target. Since it is desirable to spare the 26 epidermis and upper dermis from damage, and these occur 27 nearer the surface, it is clear that any means by which 28 the ratio of fluence at a depth compared with surface 29 fluence can be increased offers an improvement in 30 efficacy and safety. 31 32 An approach taught in current practice is to use large 33 areas of illumination. However this novel approach, 34 and the second aspect of the invention, is to use a 35 lens 15 to sharply focus the incident beam 3 to a point 36 16 around 3 mm below the surface 2 as shown in Figure

11

Although there are many scattering events as light 1 2 moves through the tissue, with the consequences outlined above, each event scatters light in a 3 4 predominantly forward direction. A sharply focused beam therefore offers some counteraction to the spread 5 induced by scattering. 6 7 8 Unfortunately, to focus the whole beam from a pulsed 9 laser such as ruby or alexandrite presents a serious 10 safety hazard; the slightest incorrect positioning of 11 the focal point would substantially increase the coherent fluence at the surface and lead to severe 12 13 damage. 14 15 Figure 3b shows an arrangement which overcomes this 16 disadvantage by passing the large area collimated beam 17 3 through an array 5 of small micro lenses 5a. These 18 lenses are of short focal length. The focusing . 19 function of this array 5 is estimated to double the 20 sub-surface flux at point 17. There is insufficient 21 energy falling within the acceptance area of an 22 individual lens 5a to present a safety hazard. 23 24 A third aspect of the invention addresses the issue of 25 light coupling into tissue. As mentioned above, the 26 use of a gel has been suggested as a way of improving 27 light coupling. Since the tissue surface is 28 microscopically uneven, applying a gel - and thus 29 essentially smoothing the surface profile to one of 30 near normal incidence to the beam - would indeed help 31 to reduce the reflection losses associated with the 32 refractive index difference between tissue and air. 33 Unfortunately this technique does not really address 34 the reason for the 'apparent' high reflectivity of

35 **36**  tissue.

12

WO 98/52481

PCT/GB98/01523

The greater portion of the apparent reflected light is 1 caused not by index mismatch but rather by transmission 2 into the tissue followed by scattering into a backward 3 direction and finally re-emergence. 4 5 Although each scattering event is predominantly in the 6 forward direction, there are, on average, some 200 such 7 events per mm penetration. As described earlier some 8 500 of the incident energy contributes to the fluence 9 at depth whilst the remaining 50% is scattered in all 10 the other directions. A half of this, that is 25% of 11 12 the total, actually finds its way out of the tissue, contributing to the apparent reflected energy. This 13 14 figure of 25% is approximate and depends on the nature of the tissue. In skin it can also vary between 15 individuals and on sites on the same individual. 16 17 However, the figure usually is between 20% and 40%. 18 19 This aspect of-the invention seeks to provide means of 20 capturing this effectively reflected light by using a 21 mirror surface 6 around the handpiece 7 and thus 22 returning the light to the tissue surface 2 once more. 2.3 This is shown in Figure 4. The area of surface that is the source of this back scattered light is larger than 24 the original illuminated area, and the emerging ray 25 26 directions 18 are spread widely. Under these 27 circumstances, only limited focusing of the light to be 28 returned to the tissue is possible. This is achieved 29 using a mirror surface 6 of a parabolic form. A 30 simpler hemispherical shape or a conical section are 31 alternatives which give adequate advantage. 32 Irrespective of shape, the action of returning the back 33 scattered light to the tissue surface effectively provides an increase in overall coupling, and thus a 34 35 reduction in the applied energy required to reach a 36 therapeutic level. This reduction is estimated to be

13

around 20% and therefore an initial requirement of, for 1 example, a fluence of  $20 \text{ J/cm}^2$  at the surface 2 would be 2 reduced to around 16 J/cm<sup>2</sup>. 3 In summary, the embodiment shown in Figure 1 shows an 5 apparatus 1 incorporating a combination of the 6 7 improvements outlined above. This apparatus 1 includes 8 means 4 for drawing up an annulus of tissue, thereby 9 both stretching and thinning the central zone above a This central zone is illuminated with a 10 collimated laser beam 3 passing through an array of 11 micro lenses 5. Typically these lenses may be 1mm in 12 diameter and have a focal length of around 10mm. The 13 14 delivery handpiece 7 is provided with a means 6 of 15 reflecting back any scattered light returning from the 16 tissue surface. 17 18 This embodiment incorporates all the improvements Each individual improvement, that is the 19 described. annular ring 4, the array of micro lenses 5 and the 20 reflector 6 may be separately applied in other simpler 21 22 embodiments without detracting from their individual ' 23 novelty. 24 25 Each individual improvement may also be combined with 26 other established methods such as tissue precooling. 27 Other techniques, for example, for stretching the skin, would be included in the general principles outlined 28 29 here. 30 31 The embodiment described above offers significant advantages to the process of hair removal with lasers 32 33 , or other optical means. Specifically these include a 34 change in the distribution of light to increase the 35 flux density at significant depths of, for example, 36 between 1 and 3 millimetres, a reduction in the blood

14

volume in the illuminated area and an increase in the
effective light flux coupled to the skin. Thus
selectivity is improved and the optical energy from the
laser or other source is reduced. The embodiment shows
specific means for achieving these advantages.

Improvements and modifications may be made to the above
without departing from the scope of the invention.

21		member comprising an inverted annular channel is
22		placed around the target area and the vacuum
23		member is evacuated to draw the skin into the
24		annular channel.
25		
26	20.	A method as claimed in any one of Claims 15 to 19
27		wherein said collimated light beam is passed
28		through an array of coplanar lenses positioned
29		above the skin surface.
30		
31	21.	A method as claimed in Claim 20 wherein said
32		lenses are microlenses of short focal length.
33		
34	22.	A method as claimed in Claim 20 or Claim 21
35		wherein said array is adapted to increase the flux
36		density at a predetermined depth below the skin

PCT/GB98/01523

1		surface.
2		
3	23.	A method as claimed in Claim 22 wherein said
4		predetermined depth is between 1 and 5 mm,
5		preferably between 2 and 4 mm.
6		
7	24.	A method as claimed in any one of Claims 15 to 23
8		wherein the light beam is a laser light beam.
9		
10	25.	${\bf A}$ method as claimed in any preceding claim further
11		comprising the steps of precooling the tissue
12		and/or selective cooling of the epidermis and/or
13		use of optical transmitting gels and/or use of
14		convex shaped applicators and/or use of devices to
15		draw folds of skin which may receive radiation
16		from either side.

# INTERNATIONAL SEARCH REPORT

Box I	Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This Inte	ernational Search Report has not been eatabliehed in respect of certain claims under Article 17(2)(a) for the following reasons:
1. <b>n</b>	Claims Nos.: 14-25 because they relate to subject matter not required to be searched by this Authority, namely:  Rule 39.1(4)
2. ري	Claims Nos.: because they relate to parts of the International Application that do not comply with the proscribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. [] C	laims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II	Observations where unity of invention is lacking (Continuation of item 2 of first sheet)
This Inte	rnational Searching Authority found multiple inventions in this international application, as follows:
1.	As all required additional search lees were timely paid by the applicant, this International Search Report coirers all searchable claims.
2.	As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional lee.
3.	As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4.	No required additional search lees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
Remark	on Protest  [] The additional search fees were accompanied by the applicant 's protest.  No protest accompanied the payment of additional search lees.
